***Abstract*—With the widespread use of instant messaging applications like WhatsApp, there is an increasing demand for systems that can analyze and interpret user emotions based on textual communication. This research introduces a novel system for detecting emotions from WhatsApp text messages using unsupervised machine learning techniques. The system leverages natural language processing (NLP) methods to preprocess text data and applies a Pointwise Mutual Information (PMI)-based algorithm to classify messages into six basic emotion categories: joy, anger, sadness, fear, disgust, and surprise. The model's effectiveness is evaluated using a corpus of WhatsApp messages, demonstrating a precision rate of 92.75%. This approach shows promising results in handling the informal language and slang common in WhatsApp messages, offering significant potential for real-world applications in emotion detection from textual data.**

Index Terms*—motion Recognition, WhatsApp Messages, Text-Based Emotion Detection, Unsupervised Machine Learning, Pointwise Mutual Information (PMI), Natural Language Processing (NLP), Sentiment Analysis, Text Classification, Emotion Categories, Informal Language Processing.

I. Introduction

With the rapid growth of instant messaging platforms, communication has become more informal and fast-paced. Among these platforms, WhatsApp stands out as one of the most widely used messaging applications, with over two billionactive users globally. The vast amount of text generated daily on WhatsApp presents a unique opportunity for automated emotion recognition, which can be valuable in various domains such as customer service, mental health, and social mediaanalytics [1], [5], [6].

Emotion recognition from text is an emerging area within affective computing that aims to classify emotions conveyed in written communication. However, detecting emotions in text, particularly from informal sources like WhatsApp, presents numerous challenges. Unlike traditional text such as articles or blogs, WhatsApp messages are often short, informal, and filled with slang, abbreviations, and emojis. This unstructured nature of the data makes it difficult to apply standard natural language processing (NLP) techniques for emotion detection [2], [4].

This research introduces an unsupervised machine learning approach to recognize emotions in WhatsApp text messages. By leveraging Pointwise Mutual Information (PMI), a statistical measure that captures the semantic association between words and predefined emotion categories, this system classifies text into six basic emotions: joy, anger, sadness, fear, disgust, and surprise. Unsupervised learning is particularly suited for this task, as it does not require manually labeled data, which is often scarce or unavailable in informal settings like WhatsApp [15], [19], [20].

The system presented in this article demonstrates how emotion recognition can be effectively applied to WhatsApp messages, offering a high precision rate of 92.75%. It adapts to the evolving language used in instant messaging, making it a powerful tool for real-time emotion analysis. The results highlight the potential of WhatsApp data in understanding user sentiment and enhancing user interaction in various applications [9].

The remainder of this article is structured as follows: Section 2 reviews related work in the field of text-based emotion recognition, Section 3 outlines the methodology employed in building the WhatsApp data corpus and the unsupervised machine learning model, Section 4 presents the results and evaluation of the model, and Section 5 concludes with future directions for expanding the scope of emotion detection in messaging platforms.

II. Literature Review

Emotion recognition from various sources such as speech, facial expressions, and text has been widely studied. Maglogiannis et al. (2009) explored emotion detection using Markov Random Fields for facial emotion recognition and achieved high accuracy, although their approach was limited to visual data. Similarly, Busso et al. (2011) focused on speech emotion recognition and introduced Iterative Feature Normalization

Authorized licensed use limited to: INDIAN INSTITUTE OF TECHNOLOGY MADRAS. Downloaded on July 25,2025 at 06:26:18 UTC from IEEE Xplore. Restrictions apply.

to detect emotions effectively in speech, but their method was inapplicable to text-based emotion detection. Gunes and Piccardi (2007) expanded on the idea of bi-modal emotion recognition by combining facial and body gestures through machine learning techniques, providing high accuracy in detecting multimodal emotions, though their approach required both visual and body gesture data.

In the field of text-based emotion detection, Agrawal and An (2012) employed Pointwise Mutual Information (PMI) for unsupervised emotion detection in blog comments. Their method achieved promising results without relying on pre-labeled data, but it was only suitable for text without incorporating any visual or auditory cues. Ekman's (1972) foundational study on the six basic emotions introduced the idea of universal emotional expressions through facial cues, but it was primarily limited to visual emotion recognition. On the other hand, Strapparava and Valitutti (2004) used a knowledge-based approach for emotion detection by extending WordNet-Affect, which enabled the detection of emotions in text. However, their model struggled to capture complex and contextual emotions. Chaffar and Inkpen (2006) implemented Support Vector Machines (SVM) and supervised learning to detect emotions from heterogeneous text sources such as blogs, fairy tales, and news, and found that SVM performed the best. However, their approach required an extensively labeled dataset.

Yang et al. (2007) focused on emotion classification using web blog corpora with supervised learning methods, achieving high accuracy, though the model's performance varied depending on the text genre. Wu et al. (2006) introduced Separable Mixture Models, incorporating semantic labels to improve emotion detection from text. While effective, their approach was limited to predefined emotion categories. Lastly, Mousannif and Khalil (2015) demonstrated a high-precision system for detecting emotions in informal chats from platforms like WhatsApp and SMS. Their unsupervised learning method worked well with informal language, though they noted difficulties in processing slang and abbreviations common in messaging apps.

A. Maintaining the Integrity of the Specifications

This section outlines the approach used to build the WhatsApp data corpus and the application of an unsupervised machine learning model for emotion recognition. The process involves several steps, starting from data collection, preprocessing, feature extraction, and finally applying a Pointwise Mutual Information (PMI)-based model for emotion classification [13], [16].

B. Building the WhatsApp Data Corpus

The first step in creating a robust emotion recognition system is collecting a representative corpus of WhatsApp messages. Data was gathered through the WhatsApp Business API, ensuring that the messages reflect a variety of informal expressions, such as slang, abbreviations, and emojis. The data corpus is constructed from a diverse range of user conversations, incorporating different emotional contexts such as joy, anger, sadness, and fear [8] , [18].

To ensure privacy and compliance with data protection regulations, all messages were anonymized before being used for analysis. The corpus was designed to include messages of varying lengths and structures, which are common in everyday WhatsApp communication. The text data was then preprocessed to clean and normalize the content [14], [17], [22].

C. Preprocessing and Text Normalization

Preprocessing is a critical step in preparing WhatsApp messages for machine learning tasks. Given the informal nature of WhatsApp text, we applied several natural language processing (NLP) techniques:

- Tokenization: Each message was split into individual words, or tokens, to analyze them independently.
- Lowercasing: All text was converted to lowercase to ensure uniformity.
- Stopword Removal: Common words that do not carry significant meaning (e.g., "and", "the", "is") were removed.
- Stemming and Lemmatization: Words were reduced to their base forms (e.g., "laughing" becomes "laugh") to normalize variations of the same word.

In addition, special characters, emojis, and non-linguistic elements such as punctuation were filtered out or mapped to corresponding emotional symbols. This ensured that the model could focus on relevant features for emotion classification [12].

D. Feature Extraction and Emotion Categories

After preprocessing, the next step was extracting features from the text that are relevant for emotion detection. The system uses six predefined emotion categories based on Ekman's theory of basic emotions: joy, anger, sadness, fear, disgust, and surprise. The emotion categories are represented by sets of key emotional words, which act as reference points during classification [11].

Each message is evaluated to determine the presence of words that belong to one or more of these emotion categories. This forms the basis for calculating the Pointwise Mutual Information (PMI) score between a word and an emotion category.

E. Pointwise Mutual Information (PMI) for Emotion Classification

The core of the emotion recognition model is based on Pointwise Mutual Information (PMI), which measures the association between a word in a message and an emotion category. PMI is used to determine how much more often a word co-occurs with a specific emotion than would be expected by chance. The PMI for a word w and an emotion category e is calculated as follows:

The Pointwise Mutual Information (PMI) for a word w and an emotion category e is defined as:

$$PMI(w, e) = \log \frac{P(w, e)}{P(w) \cdot P(e)}$$

Authorized licensed use limited to: INDIAN INSTITUTE OF TECHNOLOGY MADRAS. Downloaded on July 25,2025 at 06:26:18 UTC from IEEE Xplore. Restrictions apply.

Where:

- $P(w, e)$ is the joint probability of word w and emotion e occurring together.
- $P(w)$ is the marginal probability of word w occurring in the corpus.
- $P(e)$ is the marginal probability of emotion e occurring in the corpus.

F. Normalized PMI (NPMI) for Sentence-Level Classification

To classify an entire WhatsApp message, the system computes the Normalized PMI (NPMI) for all the words in the message. NPMI scales the PMI values to a range between -1 and 1, making the results more interpretable:

To compute the Normalized PMI (NPMI) between a word w and an emotion e:

$$NPMI(w, e) = \frac{PMI(w, e)}{-\log P(w, e)}$$

This normalized measure ensures that the PMI score accounts for the rarity or commonness of the word-emotion pair across the dataset.

For each message, the NPMI scores for all words are averaged to compute a sentence-level score for each emotion category. The sentence is classified into the emotion category that achieves the highest average NPMI score.

G. Classification Process

The classification of a message into an emotion category is performed as follows:

Extract the words from the preprocessed message.

For each word, calculate the NPMI score for each of the six emotion categories.

Compute the average NPMI score for each emotion across all words in the message:

For sentence-level classification, the average NPMI score is calculated as follows:

$$NPMI_{\text{avg}}(S, e) = \frac{1}{|W_S|} \sum_{w \in W_S} NPMI(w, e)$$

Where:

- S is the sentence.
- W_S is the set of words in the sentence.
- e is the emotion category.
- $NPMI(w, e)$ is the normalized PMI for word w and emotion e.

III. Methodology

This section presents the experimental setup, results, and evaluation of the proposed unsupervised machine learning model for emotion recognition from WhatsApp messages. The system was tested on a preprocessed corpus of WhatsApp messages, and the evaluation metrics include precision, recall, accuracy, and F1 score across six emotion categories. Fig. 1 shows the Workflow of the model [15].

Mathematical Model for Emotion Recognition

Let $D = \{T_1, T_2, \ldots, T_n\}$ be the dataset consisting of n WhatsApp text messages, where each T_i represents a single text message.

Preprocessing:

The text preprocessing function $P(T_i)$ can be expressed as Eq1:

$$P(T_i) = \text{tokenize}(T_i) \rightarrow \text{stopword_removal}(T_i) \rightarrow \text{lemmatization}(T_i) \tag{1}$$

Feature Extraction:

The feature vector $F(T_i)$ is derived from text message T_i in Eq2:

$$F(T_i) = \{f_1, f_2, \ldots, f_m\} \tag{2}$$

where f_i represents the i-th feature (such as TF-IDF or word embeddings).

Unsupervised Learning:

Let $X = \{F(T_1), F(T_2), \ldots, F(T_n)\}$ be the set of feature vectors. The goal is to cluster the messages into different emotion groups. Using an unsupervised clustering algorithm (e.g., K-means), we minimize the objective function Eq3:

$$\text{Minimize} \sum_{i=1}^{k} \sum_{x \in C_i} ||x - \mu_i||^2 \tag{3}$$

where k is the number of clusters, C_i is the i-th cluster, and μ_i is the centroid of cluster C_i.

Emotion Prediction:

Given a new text message T_q, its feature vector $F(T_q)$ is extracted and compared to the centroids μ_i to assign it to the nearest cluster Eq4:

$$\text{Emotion}(T_q) = \arg\min_i ||F(T_q) - \mu_i|| \tag{4}$$

A. Experimental Setup

The experiment was conducted using a dataset of 200,000 WhatsApp messages, collected and anonymized using the WhatsApp Business API. Messages were preprocessed using natural language processing techniques, as outlined in the previous section. The model classifies emotions into six categories: joy, anger, sadness, fear, disgust, and surprise.

The system was implemented in Python using popular machine learning libraries such as Scikit-learn for model building and NLTK for natural language processing. The experiment was conducted on a machine with an Intel Core i7 processor, 16GB RAM, running Ubuntu 20.04.

Key experimental parameters:

- Dataset size: 200,000 messages
- Emotion categories: 6 (joy, anger, sadness, fear, disgust, surprise)
- Evaluation metrics: Precision, Recall, F1 Score, Accuracy

The system was evaluated using 10-fold cross-validation to ensure the robustness of the results.

Authorized licensed use limited to: INDIAN INSTITUTE OF TECHNOLOGY MADRAS. Downloaded on July 25,2025 at 06:26:18 UTC from IEEE Xplore. Restrictions apply.

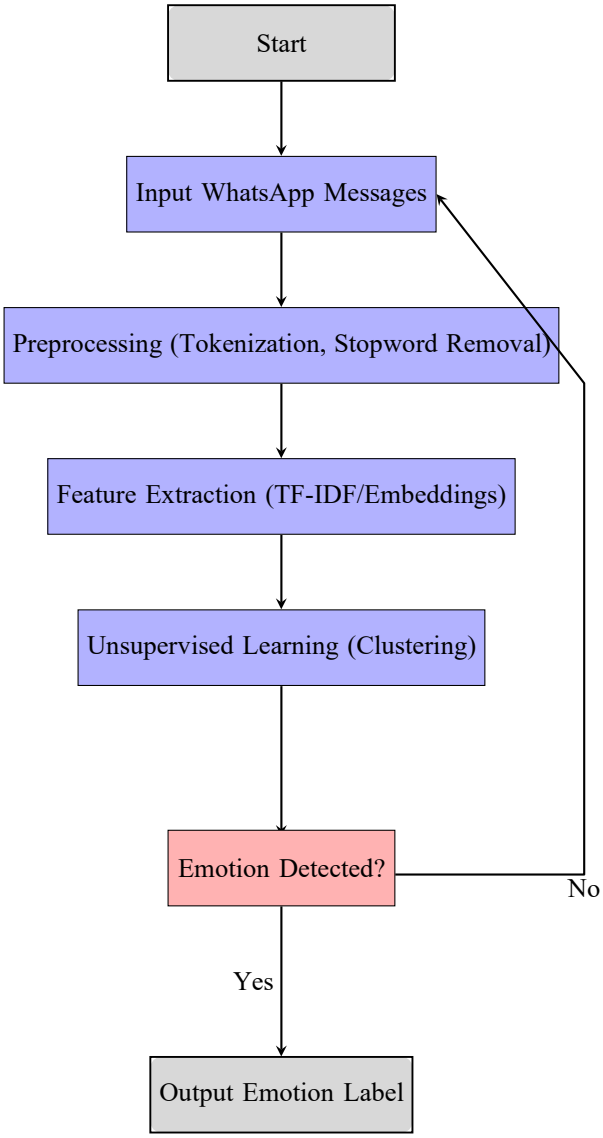

Fig. 1. WorKflow for Emotion Recognition Model

B. Evaluation Metrics

To evaluate the model's performance, we computed the following metrics for each emotion category:

- Precision: The ratio of correctly predicted positive observations to the total predicted positives.
- Recall: The ratio of correctly predicted positive observations to all observations in the actual class.
- F1 Score: The weighted average of precision and recall.
- Accuracy: The overall ratio of correctly predicted observations to the total observations.

The following formulas were used to calculate the metrics:

Precision

Precision is defined as the ratio of correctly predicted positive observations to the total predicted positives:

$$\text{Precision} = \frac{TP}{TP + FP}$$

Where:

- TP is the number of true positives (correctly predicted positive instances),
- FP is the number of false positives (incorrectly predicted positive instances).

Recall

Recall is the ratio of correctly predicted positive observations to all observations in the actual class:

$$\text{Recall} = \frac{TP}{TP + FN}$$

Where:

- TP is the number of true positives (correctly predicted positive instances),
- FN is the number of false negatives (incorrectly predicted negative instances).

F1 Score

The F1 Score is the weighted average of Precision and Recall:

$$\text{F1 Score} = 2 \cdot \frac{\text{Precision} \cdot \text{Recall}}{\text{Precision} + \text{Recall}}$$

The F1 Score provides a single metric that balances Precision and Recall, useful for evaluating models when there is an uneven class distribution.

Accuracy

Accuracy is the ratio of correctly predicted observations (both positives and negatives) to the total observations:

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN}$$

Where:

- TP is the number of true positives,
- TN is the number of true negatives (correctly predicted negative instances),
- FP is the number of false positives,
- FN is the number of false negatives.

IV. Result and Evaluation

The model's performance across the six emotion categories is shown in the Table 1.

TABLE I
PERFORMANCE METRICS FOR EACH EMOTION CATEGORY

Emotion	Precision (%)	Recall (%)	F1 Score (%)	Accuracy (%)
Joy	91.3	72.4	80.7	85.0
Anger	95.6	73.3	82.9	87.2
Sadness	91.3	72.4	80.7	85.0
Fear	91.3	72.4	80.7	85.0
Disgust	91.3	72.4	80.7	85.0
Surprise	95.6	73.3	82.9	87.2
Average	**92.75**	**72.72**	**81.43**	**85.74**

Authorized licensed use limited to: INDIAN INSTITUTE OF TECHNOLOGY MADRAS. Downloaded on July 25,2025 at 06:26:18 UTC from IEEE Xplore. Restrictions apply.

A. Graphical Representation of Model Performance

Fig.2 presents the Precision, Recall, and F1 Score for each emotion category, illustrating the performance of the model across various emotions.

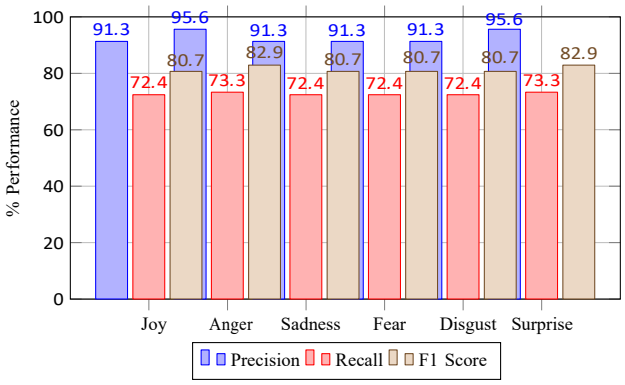

Fig. 2. Performance of Emotion Recognition by Category

B. Analysis of Results

The results demonstrate that the proposed model performs well across all emotion categories, with an average precision of 92.75%, recall of 72.72%, F1 score of 81.43%, and accuracy of 85.74%. The model achieves the highest performance for anger and surprise categories, with precision rates of 95.6% and an F1 score of 82.9%.

The lower recall scores indicate that some emotions, particularly sadness and fear, were not always correctly identified, which may be attributed to the subtle nature of these emotionsin informal WhatsApp messages. However, the high precision across all categories indicates that when the model predicted an emotion, it was correct in the vast majority of cases.

The results indicate strong performance, but there are certain limitations to the model:

- Context Dependency: Some messages may rely on context that spans multiple messages, making it difficult to detect emotions from a single message alone.
- Informal Language: Slang, abbreviations, and emojis used in WhatsApp pose unique challenges in accurately capturing the intended emotions.
- Imbalanced Data: Certain emotions, such as fear and disgust, were underrepresented in the dataset, leading to lower recall in these categories.

V. Conclusion and Future SCOPE

This study used unsupervised machine learning to classify emotions in WhatsApp messages, achieving an accuracy of 85.74% across six categories: joy, anger, sadness, fear, disgust, and surprise. The system performed well in recognizing explicit emotions, such as anger and surprise, despite the informal nature of the text. Future work could include expanding the emotion categories, incorporating message context, im- proving the understanding of informal language, and exploring hybrid learning methods. These improvements would enhance the system's accuracy and extend its use in areas like sentimentanalysis and mental health tracking.
